Chapter 5
Quorum Systems

What happens if a single server is no longer powerful enough to service all your customers? The obvious choice is to add more servers and to use the majority approach (e.g., Paxos, Chapter 1) to guarantee consistency. However, even if you buy one million servers, a client still has to access more than half of them per request! While you gain fault-tolerance, your efficiency can at most be doubled.

Do we have to give up on consistency?

Let us take a step back: We used majorities because majority sets always overlap. But are majority sets the only sets that guarantee overlap? In this chapter, we study the theory behind overlapping sets, known as quorum systems.

Definition 5.1 (quorum, quorum system). Let \( V = \{v_1, \ldots, v_n\} \) be a set of nodes. A quorum \( Q \subseteq V \) is a subset of these nodes. A quorum system \( S \subseteq 2^V \) is a set of quorums such that every two quorums intersect, i.e., \( Q_1 \cap Q_2 \neq \emptyset \) for all \( Q_1, Q_2 \in S \).

Remarks:
- When a quorum system is being used, a client selects a quorum, acquires a lock (or ticket) on all nodes of the quorum, and when done releases all locks again. The idea is that no matter which quorum is chosen, its nodes will intersect with the nodes of every other quorum.
- What can happen if two quorums try to lock their nodes at the same time?
  - A quorum system \( S \) is called minimal if \( \forall Q_1, Q_2 \in S : Q_1 \not\subseteq Q_2 \).
  - The simplest quorum system imaginable consists of just one quorum, which in turn just consists of one server. It is known as Singleton.
  - In the Majority quorum system, every quorum has \( \left\lfloor \frac{n}{2} \right\rfloor + 1 \) nodes.
  - Can you think of other simple quorum systems?

5.1 Load and Work

Definition 5.2 (access strategy). An access strategy \( Z \) defines the probability \( P_Z(Q) \) of accessing a quorum \( Q \in S \) such that \( \sum_{Q \in S} P_Z(Q) = 1 \).

Definition 5.3 (load).
- The load of access strategy \( Z \) on a node \( v_i \) is \( L_Z(v_i) = \sum_{Q \in S, v_i \in Q} P_Z(Q) \).
- The load induced by access strategy \( Z \) on a quorum system \( S \) is the maximal load induced by \( Z \) on any node in \( S \), i.e., \( L_Z(S) = \max_{v_i \in S} L_Z(v_i) \).
- The load of a quorum system \( S \) is \( L(S) = \min_{Q} L_Z(S) \).

Definition 5.4 (work).
- The work of a quorum \( Q \in S \) is the number of nodes in \( Q \), \( W(Q) = |Q| \).
- The work induced by access strategy \( Z \) on a quorum system \( S \) is the expected number of nodes accessed, i.e., \( W_Z(S) = \sum_{Q \in S} P_Z(Q) \cdot W(Q) \).
- The work of a quorum system \( S \) is \( W(S) = \min_Z W_Z(S) \).

Remarks:
- Note that you cannot choose different access strategies \( Z \) for work and load, you have to pick a single \( Z \) for both.
- We illustrate the above concepts with a small example. Let \( V = \{v_1, v_2, v_3, v_4, v_5\} \) and \( S = \{Q_1, Q_2, Q_3, Q_4\} \), with \( Q_1 = \{v_1, v_2\} \), \( Q_2 = \{v_1, v_3, v_4\} \), \( Q_3 = \{v_2, v_3, v_5\} \), \( Q_4 = \{v_2, v_4, v_5\} \). If we choose the access strategy \( Z \) such that \( P_Z(Q_1) = 1/2 \) and \( P_Z(Q_2) = P_Z(Q_3) = P_Z(Q_4) = 1/6 \), then the node with the highest load is \( v_2 \) with \( L_Z(v_2) = 1/2 + 1/6 + 1/6 = 5/6 \), i.e., \( L_Z(S) = 5/6 \). Regarding work, we have \( W_Z(S) = 1/2 \cdot 2 + 1/6 \cdot 3 + 1/6 \cdot 3 = 15/6 \).
  - Can you come up with a better access strategy for \( S \)?
  - If every quorum \( Q \) in a quorum system \( S \) has the same number of elements, \( S \) is called uniform.
  - What is the minimum load a quorum system can have?

</tr>
</tbody>
</table>

Table 5.3: First comparison of the Singleton and Majority quorum systems.

Note that the Singleton quorum system can be a good choice when the failure probability of every single node is > 1/2.
Theorem 5.6. Let $S$ be a quorum system. Then $L(S) \geq 1/\sqrt{n}$ holds.

Proof. Let $Q = \{v_1, \ldots, v_q\}$ be a quorum of minimal size in $S$, with sizes $|Q| = q$ and $|S| = n$. Let $Z$ be an access strategy for $S$. Every other quorum in $S$ intersects in at least one element with this quorum $Q$. Each time a quorum is accessed, at least one node in $Q$ is accessed as well, yielding a lower bound of $L_Z(v_i) \geq 1/q$ for some $v_i \in Q$.

Furthermore, as $Q$ is minimal, at least $q$ nodes need to be accessed, yielding $W(S) \geq q$. Thus, $L_Z(v_i) \geq q/n$ for some $v_i \in Q$, as each time $q$ nodes are accessed, the load of the most accessed node is at least $q/n$.

Combining both ideas leads to $L_Z(S) \geq \max(1/q, q/n) \Rightarrow L_Z(S) \geq 1/\sqrt{n}$.

Thus, $L(S) \geq 1/\sqrt{n}$, as $Z$ can be any access strategy.

Remarks:

• Can we achieve this load?

5.2 Grid Quorum Systems

Definition 5.7 (Basic Grid quorum system). Assume $\sqrt{n} \in \mathbb{N}$, and arrange the $n$ nodes in a square matrix with side length of $\sqrt{n}$, i.e., in a grid. The basic Grid quorum system consists of $\sqrt{n}$ quorums, with each containing the full row $i$ and the full column $i$, for $1 \leq i \leq \sqrt{n}$.

Figure 5.8: The basic version of the Grid quorum system, where each quorum $Q_i$ with $1 \leq i \leq \sqrt{n}$ uses row $i$ and column $i$. The size of each quorum is $2\sqrt{n} - 1$ and two quorums overlap in exactly two nodes. Thus, when the access strategy $Z$ is uniform (i.e., the probability of each quorum is $1/\sqrt{n}$), the work is $2\sqrt{n} - 1$, and the load of every node is in $\Theta(1/\sqrt{n})$.

Remarks:

• Consider the right picture in Figure 5.8: The two quorums intersect in two nodes. If both quorums were to be accessed at the same time, it is not guaranteed that at least one quorum will lock all of its nodes, as they could enter a deadlock!

• In the case of just two quorums, one could solve this by letting the quorums just intersect in one node, see Figure 5.9. However, already with three quorums the same situation could occur again, progress is not guaranteed!

• However, by deviating from the “access all at once” strategy, we can guarantee progress if the nodes are totally ordered!

Theorem 5.11. If each quorum is accessed by Algorithm 5.10, at least one quorum will obtain a lock for all of its nodes.

Proof. We prove the theorem by contradiction. Assume no quorum can make progress, i.e., for every quorum we have: At least one of its nodes is locked by another quorum. Let $v$ be the node with the highest identifier that is locked by some quorum $Q$. Observe that $Q$ already locked all of its nodes with a smaller identifier than $v$, otherwise $Q$ would have restarted. As all nodes with a higher identifier than $v$ are not locked, $Q$ either has locked all of its nodes or can make progress – a contradiction. As the set of nodes is finite, one quorum will eventually be able to lock all of its nodes.

Remarks:

• But now we are back to sequential accesses in a distributed system? Let’s do it concurrently with the same idea, i.e., resolving conflicts by the ordering of the nodes. Then, a quorum that locked the highest identifier so far can always make progress!

Theorem 5.13. If the nodes and quorums use Algorithm 5.12, at least one quorum will obtain a lock for all of its nodes.
Algorithm 5.12 Concurrent Locking Strategy for a Quorum Q

Invariant. Let $v_Q \in Q$ be the highest identifier of a node locked by $Q$ s.t. all nodes $v_i \in Q$ with $v_i < v_Q$ are locked by $Q$ as well. Should $Q$ not have any lock, then $v_Q$ is set to 0.

1: repeat
2: Attempt to lock all nodes of the quorum $Q$
3: for each node $v \in Q$ that was not able to be locked by $Q$ do
4: exchange $v_Q$ and $v_Q'$ with the quorum $Q'$ that locked $v$
5: if $v_Q > v_Q'$ then
6: $Q'$ releases lock on $v'$ and $Q$ acquires lock on $v$
7: end if
8: until all nodes of the quorum $Q$ are locked

Proof. The proof is analogous to the proof of Theorem 5.11: Assume for contradiction that no quorum can make progress. However, at least the quorum with the highest $v_Q$ can always make progress – a contradiction! As the set of nodes is finite, at least one quorum will eventually be able to acquire a lock on all of its nodes.

Remarks:
- What if a quorum locks all of its nodes and then crashes? Is the quorum system dead now? This issue can be prevented by, e.g., using leases instead of locks: leases have a timeout, i.e., a lock is released eventually.

5.3 Fault Tolerance

Definition 5.14 (resilience). If any $f$ nodes from a quorum system $S$ can fail s.t. there is still a quorum $Q \in S$ without failed nodes, then $S$ is $f$-resilient. The largest such $f$ is the resilience $R(S)$.

Theorem 5.15. Let $S$ be a Grid quorum system where each of the $n$ quorums consists of a full row and a full column. $S$ has a resilience of $\sqrt{n} - 1$.

Proof. If all $\sqrt{n}$ nodes on the diagonal of the grid fail, then every quorum will have at least one failed node. Should less than $\sqrt{n}$ nodes fail, then there is a row and a column without failed nodes.

Remarks:
- The Grid quorum system in Theorem 5.15 is different from the Basic Grid quorum system described in Definition 5.7. In each quorum in the Basic Grid quorum system the row and column index are identical, while in the Grid quorum system of Theorem 5.15 this is not the case.

Definition 5.16 (failure probability). Assume that every node works with a fixed probability $p$ (in the following we assume concrete values, e.g. $p > 1/2$). The failure probability $F_p(S)$ of a quorum system $S$ is the probability that at least one node of every quorum fails.
Figure 5.21: A B-Grid quorum system with $n = 100$ nodes, $d = 10$ columns, $h = 5$ bands, and $r = 2$. The depicted quorum has a $d + hr - 1 = 10 + 5 \cdot 1 = 19$ nodes. If the access strategy $Z$ is chosen uniformly, then we have a work of $d + hr - 1$ and a load of $\frac{d+hr-1}{n}$. By setting $d = \sqrt{n}$ and $r = \log n$, we obtain a work of $\Theta(\sqrt{n})$ and a load of $\Theta(1/\sqrt{n})$.

**Theorem 5.22.** The asymptotic failure probability of the B-Grid quorum system is 0.

**Proof.** Suppose $n = dhr$ and the elements are arranged in a grid with $d$ columns and $h \cdot r$ rows. The B-Grid quorum system does fail if in each band a complete mini-column fails, because then it is not possible to choose a band where in each mini-column an element is still working. It also fails if in a band an element in each mini-column fails. Those events may not be independent of each other, but with the help of the union bound, we can upper bound the failure probability with the following equation:

$$F_b(S) \leq Pr\{\text{in every band a complete mini-column fails}\} + Pr\{\text{in a band at least one element of every mini-col. fails}\} \leq (d(1-p)^h + h(1-p^d)^d$$

$$F_r(S) \leq Pr\{\text{in every row a complete mini-column fails}\} \leq (n/r)^h$$

We use $d = \sqrt{n}, r = \ln d, \text{ and } 0 \leq (1-p) \leq 1/3$. Using $a^h = \mu_h^{n}$, we have $d(1-p)^h \leq d^h = \mu_h^{n/2}$, and hence for large enough $d$ the whole first term is bounded from above by $d^{h \ln d} \ll 1/\sqrt{n}$.

Regarding the second term, we have $p \geq 2/3$, and $h = d/\ln d < d$. Hence we can bound the term from above by $d(1 - d^{h+2/3})^d \approx d(1 - d^{-4})^d$. Using $(1 + t/n)^{n} \leq e$, we get (again, for large enough $d$) an upper bound of $d(1 - d^{-h})^d = d(1 - d^{-6})^d \leq d - e^{-3d} = e^{-3d} / (e^{-3d})^d \ll 1/\sqrt{n}$. In total, we have $F_b(S) \leq O(1/\sqrt{n})$. \qed

### 5.4 Byzantine Quorum Systems

While failed nodes are bad, they are still easy to deal with: just access another quorum where all nodes can respond! Byzantine nodes make life more difficult however, as they can pretend to be a regular node, i.e., one needs more sophisticated methods to deal with them. We need to ensure that the intersection of two quorums always contains a non-byezantine (correct) node and furthermore, the byzantine nodes should not be allowed to infiltrate every quorum. In

Table 5.23: Overview of the different quorum systems regarding resilience, work, load, and their asymptotic failure probability. The best entries in each row are set in bold.

**Definition 5.24** (f-disseminating). A quorum system $S$ is $f$-disseminating if (1) the intersection of two different quorums always contains $f + 1$ nodes, and (2) for any set of $f$ byzantine nodes, there is at least one quorum without byzantine nodes.

**Remarks:**
- Thanks to (2), even with $f$ byzantine nodes, the byzantine nodes cannot stop all quorums by just pretending to have crashed. At least one quorum will survive. We will also keep this assumption for the upcoming more advanced byzantine quorum systems.
- Byzantine nodes can also do something worse than crashing - they could falsify data! Nonetheless, due to (1), there is at least one non-byezantine node in every quorum intersection. If the data is self-verifying by, e.g., authentication, then this one node is enough.
- If the data is not self-verifying, then we need another mechanism.

**Definition 5.25** (f-masking). A quorum system $S$ is $f$-masking if (1) the intersection of two different quorums always contains $2f + 1$ nodes, and (2) for any set of $f$ byzantine nodes, there is at least one quorum without byzantine nodes.

**Remarks:**
- Note that except for the second condition, an $f$-masking quorum system is the same as a $2f$-disseminating system. The idea is that the non-byezantine nodes (at least $f + 1$ can outvote the byzantine ones (at most $f$), but only if all non-byezantine nodes are up-to-date!
- This raises an issue not covered yet in this chapter. If we access some quorum and update its values, this change still has to be disseminated to the other nodes in the byzantine quorum system.Opaque quorum systems deal with this issue, which are discussed at the end of this section.
5.4. BYZANTINE QUORUM SYSTEMS

- $f$-disseminating quorum systems need more than $3f$ nodes and $f$-masking quorum systems need more than $4f$ nodes. Essentially, the quorums may not contain too many nodes, and the different intersection properties lead to the different bounds.

Theorem 5.26. Let $S$ be a $f$-disseminating quorum system. Then $L(S) \geq \sqrt{(f+1)/n}$ holds.

Theorem 5.27. Let $S$ be a $f$-masking quorum system. Then $L(S) \geq (2f+1)/n$ holds.

Proofs of Theorems 5.26 and 5.27. The proofs follow the proof of Theorem 5.6, by observing that now not just one element is accessed from a minimal quorum, but $f+1$ or $2f+1$, respectively.

Definition 5.28 ($f$-masking Grid quorum system). A $f$-masking Grid quorum system is constructed as the grid quorum system, but each quorum contains one full column and $f+1$ rows of nodes, with $2f+1 \leq \sqrt{n}$.

Figure 5.29: An example how to choose a quorum in the $f$-masking Grid with $f = 2$, i.e., $2 + 1 = 3$ rows. The load is in $\Theta(\sqrt{n})$ when the access strategy is chosen to be uniform. Two quorums overlap by their columns intersecting each other’s rows, i.e., they overlap in at least $2f + 2$ nodes.

Remarks:
- The $f$-masking Grid nearly hits the lower bound for the load of $f$-masking quorum systems, but not quite. A small change and we will be optimal asymptotically.

Definition 5.30 ($M$-Grid quorum system). The $M$-Grid quorum system is constructed as the grid quorum as well, but each quorum contains $\sqrt{f+1}$ rows and $\sqrt{f+1}$ columns of nodes, with $f \leq \sqrt{n}$.

![Figure 5.31](image.png)

Figure 5.31: An example how to choose a quorum in the $M$-Grid with $f = 3$, i.e., 2 rows and 2 columns. The load is in $\Theta(\sqrt{n})$ when the access strategy is chosen to be uniform. Two quorums overlap with each row intersecting each other’s column, i.e., $2\sqrt{f+1} = 2f + 2$ nodes.

Corollary 5.32. The $f$-masking Grid quorum system and the $M$-Grid quorum system are $f$-masking quorum systems.

Remarks:
- We achieved nearly the same load as without byzantine nodes! However, as mentioned earlier, what happens if we access a quorum that is not up-to-date, except for the intersection with an up-to-date quorum? Surely we can fix that as well without too much loss?
- This property will be handled in the last part of this chapter by opaque quorum systems. It will ensure that the number of correct up-to-date nodes accessed will be larger than the number of out-of-date nodes combined with the byzantine nodes in the quorum (cf. (5.33.1)).

Definition 5.33 ($f$-opaque quorum system). A quorum system $S$ is $f$-opaque if the following two properties hold for any set of $f$ byzantine nodes $F$ and any two different quorums $Q_1$, $Q_2$:

$$(Q_1 \cap Q_2) \setminus F \geq (Q_2 \cap F) \cup (Q_1 \setminus Q_2) \quad (5.33.1)$$

$$(F \cap Q) = \emptyset \text{ for some } Q \in S \quad (5.33.2)$$

Theorem 5.35. Let $S$ be a $f$-opaque quorum system. Then, $n > 5f$.

Proof. Due to (5.33.2), there exists a quorum $Q_1$ with size at most $n-f$. With (5.33.1), $|Q_1| > f$ holds. Let $F_1$ be a set of $f$ (byzantine) nodes $F_1 \subseteq Q_1$, and with (5.33.2), there exists a $Q_2 \subset \setminus F_1$. Thus, $|Q_1 \cap Q_2| \leq n-2f$. With (5.33.1), $|Q_1 \cap Q_2| > f$ holds. Thus, one could choose $f$ (byzantine) nodes $F_2$ with $F_2 \subseteq (Q_1 \cap Q_2)$. Using (5.33.1) one can bound $n > 3f$ from below: $n-3f > |Q_1 \cap Q_2| - |F_2| \geq |Q_2 \cap Q_1| \cup (Q_1 \cap F_2) \geq |F_1| + |F_2| = 2f$. □
5.4. BYZANTINE QUORUM SYSTEMS

The f-masking Grid quorum system and opaque quorum systems are from [MR98], and the M-Grid quorum system was introduced in [MRW97]. Both papers also mark the start of the formal study of Byzantine quorum systems. The f-masking and the M-Grid have asymptotic failure probabilities of 1, more complex systems with better values can be found in these papers as well.

Quorum systems have also been extended to cope with nodes dynamically leaving and joining, see, e.g., the dynamic paths quorum system in [NW05].

For a further overview on quorum systems, we refer to the book by Vukolić [Vuk12] and the article by Merideth and Reiter [MR10].

This chapter was written in collaboration with Klaus-Tycho Förster.

Bibliography

Chapter Notes

Historically, a quorum is the minimum number of members of a deliberative body necessary to conduct the business of that group. Their use has inspired the introduction of quorum systems in computer science since the late 1970s/early 1980s. Early work focused on Majority quorum systems [Lam78, Gif79, Tho79], with the notion of minimality introduced shortly after [GB85]. The Grid quorum system was first considered in [Mae85], with the B-Grid being introduced in [NW94]. The latter article and [PW95] also initiated the study of load and resilience.
