Exercise 10

Lecturer: Mohsen Ghaffari

1 Pipelining

We consider an arbitrary n-node network G = (V, E) with diameter D. Moreover, we work in the CONGEST model of distributed computing where each node has an $O(\log n)$ -bit unique identifier and per round, each node can send $O(\log n)$ bits to each of its neighbors.

Exercises

- (1a) Suppose that each node $v \in V$ is given k different inputs $x_1(v), x_2(v), \ldots, x_k(v)$, each being a $\Theta(\log n)$ -bit number. The objective is for all nodes to know the outputs $y_i = \min_{v \in V} x_i(v)$, for each $i \in \{1, 2, \ldots, k\}$. Devise a deterministic distributed algorithm for this problem with round complexity O(D + k).
- (1b) Suppose there are k messages m_1, m_2, \ldots, m_k , each initially placed at an arbitrary node of the network (many or even all of the messages may be placed on the same node). Consider the following basic algorithm: per round, each node v picks one of the messages m_i that it has (from the beginning or received in the past) and sends m_i to all of its neighbors; node v will never send m_i again. Notice that a node will not send two of the messages at the same time. Prove that if we run this algorithm for O(D + k) rounds, all nodes will receive all the messages.

2 Minimum Spanning Tree

Consider an undirected connected graph G = (V, E) where n = |V|. Suppose that each node $v \in V$ has selected one of its incident edges (v, u) as the *proposal edge of* v, let us denote it $e_v = (v, u)$. For instance, in the MST algorithm of Boruvka, this would be the minimum-weight edge incident on v. Notice that the two endpoints of an edge might propose this one edge simultaneously. Consider the random process that each node flips a fair coin for itself and then, we mark the proposed edge $e_v = (v, u)$ of node v only if v draws tail and v draws head.

Exercises

- (2a) Prove that, in expectation, we mark at least n/8 edges, provided that $n \geq 2$.
- (2b) Prove that, if we contract all the marked edges, the resulting graph has at most 7n/8 nodes, in expectation, provided that $n \ge 2$.
- (2c) Consider repeating the above process for $20 \log n$ iterations: In each iteration, we contract all the marked edges, and remove self-loops. Then, select one (e.g., min-weight) incident edge per new node, and repeat the marking process as above using one coin toss per each new node. Use (2b) to prove that, after $20 \log n$ iterations, with high probability, we have contracted everything to a single node.
