Exercise Sheet 6

1 Soccer Betting

The *FC Basel* soccer club is a particularly moody team. Upon winning a game, they tend to win subsequent games. After losing a game, however, they often end up losing the next game as well. A group of international scientists, consisting of soccer experts, mathematicians, and psychologists, has recently conducted a thorough analysis of this behavior. In particular, they have discovered that upon winning a game, the FCB wins the next game with a probability of 0.6 as well. With probabilities 0.2 each, the next game will be a tie or a loss. After a loss, the FCB will win/tie/lose its next game with probability 0.1/0.2/0.7, respectively. Finally, after a tie, the next game being a win or a loss is equally probable. The probability that the next game also ends up being a tie is 0.4.

- a) Model the FCB's moodiness using a Markov chain.
- b) In *two games* from now (they will play one game in between), the FCB will play against the FC Zurich. The Swiss TOTO offers you the following odds:
Win: 3.5 Tie: 4.0 Loss: 1.5
Given that the FCB won the game three games ago, but lost the last two games, what would be your bet? Why?
- c) More recent studies have shown that the FCB is even moodier than expected. In fact, after losing *two games in a row*, the probability of winning its next game reduces to 0.05, that of getting a tie to 0.1. Change your Markov chain model to incorporate the new findings. How does the change influence your bet?

2 Probability of Arrival

In the script, there is a lemma saying that the probability of arrival in a markov chain can be computed using the formula

$$f_{ij} = p_{ij} + \sum_{k:k \neq j} p_{ik} f_{kj} .$$

Prove this lemma.

3 Basketball [Exam]

Mario, Luigi and Trudy meet to play basketball. To improve their scoring abilities, Mario suggests the following game: Each player has to score m times. After each miss, he has to perform 10 push-ups.

- a) Assume that Mario always scores with a constant probability p . How many push-ups does he do in expectation in his game?
- b) Luigi wants to show that he is better and wants to score m times in sequence. After each miss, he performs 10 push-ups as well, and then tries again to score m times in a row. How many push-ups does Luigi do in expectation, assuming he also scores with a constant probability p ?
- c) Trudy accepts Luigi's game and tries to score $m = 3$ times in a row. But Trudy is a bit lazy and gives up as soon as she has missed two times in a row. Trudy scores with constant probability $p = 0.5$.
 - (i) What is the probability that Trudy scores $m = 3$ times in a row? What is the probability that she gives up?
 - (ii) How many push-ups does Trudy do in expectation?

Hint:
$$\sum_{i=1}^{\infty} i \cdot q^{i-1} = \frac{1}{(1-q)^2} \quad \text{for } |q| < 1$$
