# 1 Pumping Lemma [Exam]

#### The Pumping Lemma in a Nutshell

Given a language L, assume for contradiction that L is regular and has the pumping length p. Construct a suitable word  $w \in L$  with  $|w| \ge p$  ("there exists  $w \in L$ ") and show that for all divisions of w into three parts, w = xyz, with  $|x| \ge 0$ ,  $|y| \ge 1$ , and  $|xy| \le p$ , there exists a pumping exponent  $i \ge 0$  such that  $w' = xy^i z \notin L$ . If this is the case, L is not regular.

Language  $L_1$  can be shown to be non-regular using the pumping lemma. Assume for contradiction that  $L_1$  is regular and let p be the corresponding pumping length. Choose w to be the word  $0110^{p}1^{p}$ . Because w is an element of  $L_1$  and has length more than p, the pumping lemma guarantees that w can be split into three parts, w = xyz, where  $|xy| \leq p$  and for any  $i \geq 0$ , we have  $xy^{i}z \in L_1$ . In order to obtain the contradiction, we must prove that for every possible partition into three parts w = xyz where  $|xy| \leq p$ , the word w cannot be pumped. We therefore consider the various cases.

- a) If y starts anywhere within the first three symbols (i.e. 011) of w, deleting y (pumping with i = 0) creates a word with an illegal prefix (e.g.  $10^p 1^p$  for y = 01).
- b) If y consists of only 0s from the second block, the word  $w' = xy^2 z$  has more 0s than 1s in the last |w'| 3 symbols and hence  $c \neq d$ .

Note that y cannot contain 1s from the second block because of the requirement  $|xy| \leq p$ .

We have shown that for all possible divisions of w into three parts, the pumped word is not in  $L_1$ . Therefore,  $L_1$  cannot be regular and we have a contradiction.

#### Be Careful!

The argumentation above is based on the closure properties of regular languages and only works in the direction presented. That is, for an operator  $\diamond \in \{\cup, \cap, \bullet\}$ , we have:

If  $L_1$  and  $L_2$  are regular, then  $L = L_1 \diamond L_2$  is also regular.

If either  $L_1$  or  $L_2$  or both are non-regular, we cannot deduce the non-regularity of L or vice-versa. Moreover, L being regular does not imply that  $L_1$  and  $L_2$  are regular as well. This may sound counter-intuitive which is why we give examples for the three operators.

•  $L = L_1 \cup L_2$ : Let  $L_1$  be any non-regular language and  $L_2$  its complement. Then  $L = \Sigma^*$  is regular.

- $L = L_1 \cap L_2$ : Let  $L_1$  be any non-regular language and  $L_2$  its complement. Then  $L = \emptyset$  is regular.
- $L = L_1 \bullet L_2$ : Let  $L_1 = \{a^*\}$  (a regular language) and  $L_2 = \{a^p \mid p \text{ is prime}\}$  (a non-regular language) then  $L = \{aaa^*\}$  is regular.

Hence, to prove that a language  $L_x$  is non-regular, you assume it to be regular for contradiction. Then you combine it with a *regular* language  $L_r$  to obtain a language  $L = L_x \diamond L_r$ . If L is non-regular,  $L_x$  could not have been regular either.

## 2 Deterministic Finite Automata [Exam]

We could use the systematic transformation scheme presented in the lecture (slide 1/75). Considering the large number of states, however, this will easily lead to an explosion of states in the derandomized automaton. Hence, we build the deterministic finite automaton in a step-wise manner, only creating those states that are actually required: Initially, the automaton requires a 0. Subsequently, only a 1 is accepted. Including the various transitions, this 1 can lead to three different states, namely states 2, 3, and 4.

In any of the states 2, 3, and 4, only a 1 is accepted. Assume that the automaton is currently in state 2, this 1 can lead to states  $\{2,3,4\}$  when including all  $\varepsilon$ -transitions. When in state 3, the 1 leads to states  $\{2,3,4,5\}$  and finally, when being in state 4, the reachable states given a 1 are  $\{2,3,4\}$ . Hence, a 1 leads from state  $\{2,3,4\}$  to state  $\{2,3,4,5\}$ . Repeating the same process for state  $\{2,3,4,5\}$ , we can see that, again, only a 1 is accepted, which leads to state  $\{2,3,4,5,6\}$ . Because the state 6 in the original NFA was an accepting state,  $\{2,3,4,5,6\}$  is also accepting in the DFA. From state  $\{2,3,4,5,6\}$ , an additional 1 will lead to another accepting state  $\{1,2,3,4,5,6\}$ . And from this state, any subsequent 1 returns to state  $\{1,2,3,4,5,6\}$  as well.

$$\rightarrow \underbrace{\{1\}}_{0} \underbrace{\{2,4\}}_{1} \underbrace{1}_{\{2,3,4\}}_{1} \underbrace{\{2,3,4\}}_{4,5\}}_{1} \underbrace{\{2,3,4,1\}}_{1} \underbrace{\{2,3,4,1\}}_{4,5,6\}}_{1} \underbrace{\{1,2,3,4,1\}}_{1} \underbrace{\{1,2,3,4,1\}}_$$

What happens if a 0 occurs in the input? This is feasible only when the deterministic state includes either state 1 or state 6. In state  $\{2, 3, 4, 5, 6\}$ , a 0 necessarily leads to state  $\{4\}$ , whereas in state  $\{1, 2, 3, 4, 5, 6\}$  a 0 leads to state  $\{2, 3, 4\}$ . In both of these states, the only acceptable input symbol is a 1 and leads to the state  $\{2, 3, 4\}$ . Hence, the deterministic finite automaton looks like this:

It can easily be seen, that first the states  $\{4\}$ ,  $\{2,4\}$  and then the states  $\{2,3,4,5,6\}$ ,  $\{1,2,3,4,5,6\}$  can be merged and hence, the automaton can be reduced to the one shown in the next figure.

This is not a DFA yet, because the crash state is still missing. The final deterministic automaton looks like this:

## 3 Transforming Automata [Exam]

The regular expression can be obtained from the finite automaton using the transformation presented in the script on slide 1/85. After ripping out state  $q_2$ , the corresponding GNFA looks like this:

After also removing state  $q_1$ , the GNFA looks as follows.

Eliminating the last state  $q_3$  yields the final solution, which is  $(01^*0)^*1(0 \cup 11^*0(01^*0)^*1)^*$ .

*Note:* Ripping out the interior states in a different order yields a distinct yet equivalent regular expression. The order  $q_3, q_2, q_1$ , for example, results in  $((0 \cup 10^*1)1^*0)^*10^*$ .

### 4 Pumping Lemma

Choose  $w = 1^p 02^p \in L$ . Let w = xyz with  $|xy| \leq p$  and  $|y| \geq 1$  (pumping lemma). Because of  $|xy| \leq p$ , xy can only consist of 1s. According to the pumping lemma, we should have  $xy^i z \in L$  for all  $i \geq 0$ . However, by choosing i = 0 we delete at least one 1 and get a word  $w' = 1^{p-|y|} 02^p$ 

with  $|y| \ge 1$ . w' is not in L since it has fewer 1s than 2s. This means that w is not pumpable and hence, L(G) is not regular.

Since *every* regular language is also context-free, we can choose an arbitrary regular language. For example, we can choose the language  $L = \{0^n 1, n \ge 1\}$  which is clearly regular. A context-free grammar for this language uses only the production  $S \to 0S \mid 1$ .
